Canada

Canadian Technical Report of Fisheries and Aquatic Sciences

Technical reports contain scientific and technical information that contributes to existing knowledge but which is not normally appropriate for primary literature. Technical reports are directed primarily toward a worldwide audience and have an international distribution. No restriction is placed on subject matter and the series reflects the broad interests and policies of Fisheries and Oceans Canada, namely, fisheries and aquatic sciences.

Technical reports may be cited as full publications. The correct citation appears above the abstract of each report. Each report is abstracted in the data base *Aquatic Sciences and Fisheries Abstracts*.

Technical reports are produced regionally but are numbered nationally. Requests for individual reports will be filled by the issuing establishment listed on the front cover and title page.

Numbers 1-456 in this series were issued as Technical Reports of the Fisheries Research Board of Canada. Numbers 457-714 were issued as Department of the Environment, Fisheries and Marine Service, Research and Development Directorate Technical Reports. Numbers 715-924 were issued as Department of Fisheries and Environment, Fisheries and Marine Service Technical Reports. The current series name was changed with report number 925.

Rapport technique canadien des sciences halieutiques et aquatiques

Les rapports techniques contiennent des renseignements scientifiques et techniques qui constituent une contribution aux connaissances actuelles, mais qui ne sont pas normalement appropriés pour la publication dans un journal scientifique. Les rapports techniques sont destinés essentiellement à un public international et ils sont distribués à cet échelon. Il n'y a aucune restriction quant au sujet; de fait, la série reflète la vaste gamme des intérêts et des politiques de Pêches et Océans Canada, c'est-à-dire les sciences halieutiques et aquatiques.

Les rapports techniques peuvent être cités comme des publications à part entière. Le titre exact figure au-dessus du résumé de chaque rapport. Les rapports techniques sont résumés dans la base de données *Résumés des sciences aquatiques et halieutiques*.

Les rapports techniques sont produits à l'échelon régional, mais numérotés à l'échelon national. Les demandes de rapports seront satisfaites par l'établissement auteur dont le nom figure sur la couverture et la page du titre.

Les numéros 1 à 456 de cette série ont été publiés à titre de Rapports techniques de l'Office des recherches sur les pêcheries du Canada. Les numéros 457 à 714 sont parus à titre de Rapports techniques de la Direction générale de la recherche et du développement, Service des pêches et de la mer, ministère de l'Environnement. Les numéros 715 à 924 ont été publiés à titre de Rapports techniques du Service des pêches et de la mer, ministère des Pêches et de l'Environnement. Le nom actuel de la série a été établi lors de la parution du numéro 925.

ABSTRACT

Simard, Y., Roy, N., Giard, S., and Yayla, M. 2014. Canadian year-round shipping traffic atlas for 2013: Volume 1, East Coast marine waters. Can. Tech. Rep. Fish. Aquat. Sci. 3091(Vol.1)E: xviii + 327 pp.

The Automatic Identification System (AIS) ship-tracking data collected by Fisheries and Oceans Canada's (DFO) Canadian Coast Guard (CCG) in southern Canadian waters were used to map traffic density throughout 2013. The region considered in this report is eastern Canadian marine waters east of Ile d'Orléans near Québec City in the St. Lawrence Estuary. The AIS traffic maps are provided for the whole year and by month. For each time period, maps of daily traffic density are provided for all vessel traffic and selectively for seven vessel types, five vessel length classes, and five sailing speed classes. The data were binned using a common metric of ship-h per 1×1 km grid cell per day for all maps. The cumulative histogram of traffic density, total area with traffic, and the sum of daily traffic density are provided for each map. The atlas contains a total of 299 traffic maps.

RÉSUMÉ

Simard, Y., Roy, N., Giard, S., and Yayla, M. 2014. Canadian year-round shipping traffic atlas for 2013: Volume 1, East Coast marine waters. Can. Tech. Rep. Fish. Aquat. Sci. 3091(Vol.1)E: xviii + 327 pp.

Les données du système AIS (*Automatic Identification System*) de suivi de la navigation maritime récoltées par la Garde Côtière canadienne du ministère des Pêches et des Océans (MPO) dans les eaux méridionales canadiennes sont utilisées pour cartographier l'intensité du trafic au cours de 2013. La région considérée dans ce rapport est celle des eaux marines canadiennes à l'est de l'Ile d'Orléans, près de Québec dans l'estuaire du Saint-Laurent. Les cartes du trafic AIS sont fournies pour l'année entière ainsi que par mois. Pour chaque période, les cartes sont fournies pour le trafic total ainsi que séparément pour sept types de navires, cinq classes de longueur de navire et cinq classes de vitesse de transit. Une métrique commune, navire-h par cellule de 1×1 km par jour, est utilisée pour toutes les cartes. L'histogramme cumulé de la densité du trafic, l'aire totale avec trafic et la somme du trafic quotidien sont fournis pour chaque carte. L'atlas renferme un total de 299 cartes de trafic.

1. INTRODUCTION

Shipping is one of several human uses of deep oceans, continental shelves, and inland waters to transport goods that are essential to the world economy. The world merchandise trade increases about two times faster than the world gross domestic product (GDP) (UNCTAD 2013). With three bordering oceans, large marginal seas and straits, and an extended network of inland waters, Canada has extensive domestic and international cargo shipping. The worldwide growth rate of this industry changed from high in the 2000's to stagnant or negative after the 2008 global economic crisis (UNCTAD 2013). The amount of transported cargo and the number of ships peaked in 2008, following a seven-fold increase since 2000. In January 2013, the transported cargo and number of ships had respectively decreased to 40% and 33% of their 2008 peaks (UNCTAD 2013; their Table 2.10, p. 62-63.). The average ship size has generally increased. This is particularly evident for general cargo ships and container vessels; the size of these latter has almost doubled since 2000. More than half of the global fleet is composed of new ships (< 10-years old).

Shipping can have various effects on several structural components and functions of aquatic ecosystems via diverse transmission pathways, including the discharge of contaminants, radiated underwater noise, introduction of aquatic invasive species, and ship strike risk (Simard et al. 2006, Clark et al. 2009, Simard et al. 2010, Bailey et al. 2012, DiBacco et al. 2012, Gervaise et al. 2012, van der Hoop et al. 2012, Greig and Abraham 2014). The probability and magnitude of such effects are often largely determined by the amount of temporal and spatial overlap of traffic density and vulnerable ecosystem components, the fleet composition, and the type of activity. Therefore, assessing the risk of shipping effects on ecosystems and their living components generally requires the temporal and spatial structure of the traffic and its composition. The possibility of assembling such information for marine spatial planning using ship position data from the satellite-based long range identification and tracking (LRIT) system with geographic information system (GIS) techniques has been assessed for Atlantic Canada (Koropatnick et al. 2012). Coarse track counts maps of LRIT-participating ships in 2010-11 were computed for distances greater than 1000 km from coastline and clearly illustrated the large-scale network of main shipping routes and the much lower traffic above 50°N. The low resolution of LRIT data and the limited information on ship identity did not allow a detailed analysis of traffic density per ship type, length class, or other characteristics. In contrast, automatic identification system AIS data provide more complete ship identity and high-resolution position data for a larger fraction of ships, which allows the building of detailed traffic maps per ship category in Canadian waters. This has never been done for shipping in Canadian waters.

The present atlas is a contribution to filling this gap for southeastern Canada by providing maps of AIS-tracked ship traffic during 2013. It documents the present state of the AIS traffic density over time and space, including by ship type, length class, and speed categories. Similar shipping traffic atlases have been published for two other southern Canadian regions: the Centre (fresh water St. Lawrence and Great Lakes) and the West Coast. They are presented in two additional volumes of the same report series (Simard et al. 2014a, b).

2. MATERIALS AND METHODS

This atlas is based on AIS information on shipping in Canadian waters and surroundings, south of $\sim 55^{\circ}$ N, from 1 January to 31 December 2013. Except for fishing vessels, AIS is compulsory by law for all ships of 500 gross tonnage (GT) or more, ships of 300 GT or more engaged on an international voyage and ships of 150 GT or more engaged on an international voyage and carrying more than 12 passengers¹. Other ships and boats can be equipped with AIS systems on a voluntary basis; these may include fishing vessels and fishing beacons. Other vessels not equipped with an AIS system are not mapped. The source of the raw shipping data and its processing are detailed below.

2.1. AIS data bank

The analyzed data are the AIS streams collected by the DFO–Coast Guard's coastal network of AIS antennas deployed to track and monitor shipping in southern Canadian waters (Fig. 1). This ship monitoring network provides a real-time, continuous stream of AIS ship positions from all southern Canadian waters ($< 55^{\circ}$ N) that is consolidated on a single server. This flow of binary data was recorded for the whole year in 2013 via a connection to the server. This data stream represents about 600 MB of data per day.

The DFO–Coast Guard's coastal AIS network covers all areas of interest for the atlas, except for offshore areas too far from the coastal AIS antennas. Although ship positions beyond 200 km of the coastline were sometimes collected, the usual maximum AIS communication ranges with coastal antenna are generally smaller (typically < 100 km). Successful AIS communication between ships and coastal antennas also depends on other factors affecting radio frequency (RF) communication range, such as proper installation and working of the systems, antenna height and lines of sight, transmission power and weather conditions. A 100% RF communication range limited to ~ 100 km is more common. An examination of the AIS antenna distribution (Fig. 1) and the computed traffic density maps indicate that Eastern Canadian waters up to ~ 100 km from the coastline seem to be well covered by the coastal AIS network. Within that range, ship trajectories were continuous and did not end in zones of null traffic. The area of the eastern Gulf of St. Lawrence, half-way between Anticosti Island and Newfoundland that is farther than 100 km from any antenna, is an area where AIS signal reception may become weak (Fig. 1). We noted such reception loss from ships sailing in this area. Interruptions shorter than 3 h were filled in by interpolations (see below). Longer interruptions were not interpolated.

Communication with the server was interrupted on occasion. Interruptions usually lasted only a few minutes and were much shorter than 3 h most of the time. These data gaps were bridged by interpolation (see below). Longer interruptions occurred on 28 days over the year; the daily traffic statistics for these days were computed with the available data that remained. Data were missing for four complete days in October. The monthly and annual averages and percentiles were computed based on the number of days for which data existed.

2.2. Data processing

The raw binary AIS data strings were read using a customized software program (in Python language) to extract the data fields shown in Table 1 and convert them into ASCII format. These data are provided chronologically for all ships independent of their location in Canadian waters. The reading and conversion program sorted them by ship and stored them in one *.csv ASCII file per day.

The retained AIS data for the atlas were first checked for errors or incomplete information, such as spurious latitude, longitude, time errors, and interruptions in data streams or absent or erroneous ship-length data. Position and time errors or gaps were corrected by interpolating from adjacent positions in the time-series. A table of the 12,645 different *mmsi* (maritime mobile service identity) numbers retrieved by the DFO–CG AIS network for all regions in 2013 with their corresponding characteristics was built. In cases of multiple entries for single *mmsi* numbers, only the entry containing the most complete information was retained.

Table 1. Data fields of ASCII-txt files extracted from the recorded raw AIS data and used in the computation of maps.

Data field	Examples	Used
Vessel type	Search and rescue vessel Tanker; no additional information Passenger; all ships of this type Cargo; all ships of this type Pleasure Other types; all ships of this type Not available Tug	√
Time (UTC)	2013-01-14 05:33:41	√
Vessel mmsi no. (maritime mobile service identity)	316278000	
Navigation status (0= underway using engine, 1= at anchor, 2 etc.)	0	
ROT (Rate of turn) (° / min)	0.0	
SOG (speed over ground) (knots)	8.7	
Latitude (°)	46.6270166667	√
Longitude (°)	-53.0057966667	√
COG (course over ground) (°)	211.0	
True heading (°)	207	
Length (m)	193	√
Breadth (m)	27	
Draught (m)	8.1	

Figure 1. Map of the study area in eastern Canada showing the outer contour of the 1 x 1 km mesh Cartesian grid (red rectangle) used for reporting the AIS shipping traffic density as delimited in Table 2 and the DFO-Coast Guard AIS antenna network, with radii of 100 km (blue circles).

The map coordinates are projected using the parameters of the Lambert conformal conic equal-area projection from Table 3.

Table 2. Latitude and longitude limits of the study area used to compute the Cartesian grid.

Grid corner bin centre	Latitude N	Longitude W
Bottom left	40.429°	70.690°
Top left	54.685°	74.118°
Bottom right	40.429°	49.110°
Top right	54.685°	45.682°

Table 3. Parameters of the Lambert conformal conic equal-area projection used for the conversion of the positions in latitude and longitude into the Cartesian grid. These parameters conform to WGS 84 datum.

Parameter	Value
Standard parallel 1	45.0° N
Standard parallel 2	50.0° N
Origin latitude	48.0° N
Origin longitude	59.9° W
Semi-major earth axis (km)	6378.137
Semi-minor earth axis (km)	6356.75231424518
Earth flattening ratio	1/298.257223563

A large proportion (42%) of the *mmsi* numbers (for the whole year of 2013 and in all regions) had missing, wrong, or zero-length data. The missing lengths were partially filled by browsing Internet sites that provide ship characteristics for *mmsi* numbers, which allowed us to retrieve 1,203 ship lengths. Lengths were still zero for 4,075 *mmsi* (32% of all *mmsi*). Approximately ~25% the 12,645 *mmsi* numbers did not contribute to the shipping traffic maps because their sailing speed was less than 1 knot, which was below the threshold for inclusion in the analysis (see below).

The AIS-SOG field was discarded because this field was sometimes missing (SOG code =1023) for some ships and was often contaminated by erroneous values. The SOG used in the atlas was therefore computed from the correct positions using a multi-step filter that removed speeds exceeding 40 knots and smoothed the fast fluctuations with a moving average on 900 s. Cross-checks with valid AIS-SOG series showed that our estimated SOG was unbiased, properly tracked the vessel speed, and was robust to non-plausible large speed fluctuations.

In AIS communication protocols, positions are not broadcasted at a constant or the same rate for all ships. The data transmission pace varies depending on the AIS class (A or B), the ship speed and the availability of the VHF transmission band. In addition, there were periods of variable durations along a ship track from which no positions were available. Therefore mapping ship traffic with AIS data is not a direct plot of broadcasted AIS positions. The time-position data must first be interpolated on a common time grid before proceeding to the mapping. Hence, before estimating the time spent by ships in a given area, all positions were interpolated to a same time step of 10 s. Position gaps along ship tracks were filled by interpolation, up to a maximum of 3 h, to account for gaps in reception either resulting from ships that were out of range of AIS coastal antenna or data stream interruptions from the server. Gaps longer than 3 h for the same ship were considered as two different tracks. (See Discussion for unwanted effects introduced by this interpolation).

The 1×1 km mesh grid used for reporting the traffic (Fig. 1) was obtained by projecting the latitude and longitude limits of the study area (Table 2) onto a Cartesian grid using a Lambert conformal conic equal-area projection using the parameters given in Table 3.

The metric used to map the AIS traffic density is *daily ship-h per 1 × 1 km grid cell*. One ship spending 0.5 h in a 1 km² grid cell in a given day would give 0.5 daily ship-h of traffic. Two ships spending 0.25 h in 1 km² grid cell would also give 0.5 daily ship-h of traffic. This metric is computed using only the ships that are underway (i.e., SOG > 1 knot [1.85 km h⁻¹]). This criterion eliminates data from anchored or docked ships as well as AIS data coming from fixed antennae or beacons, notably fishing AIS beacons, which are included in the analyzed raw AIS data bank.

The atlas maps present yearly and monthly statistics of the traffic metrics by ship category as indicated in Figure 2. For each period (i.e., the whole year and the 12 months individually), 23 traffic maps are computed for the following:

- (a) the total traffic from all vessels (the mean and the 5th, 25th, 50th, 75th, and 95th percentile of the distribution of the daily traffic density per 1 km² grid cell);
- (b) the mean traffic corresponding to seven vessel types (cargo carriers, tankers, passengers, tugs, fishing, pleasure, and others ships [including ships of unidentified types]);
- (c) the mean traffic corresponding to five different ship length classes (< 10 m, 10–50 m, 50–150 m, 150–250 m, and > 250 m);
- (d) the total traffic separated into five ship-SOG classes (2–5 knots, 5–10 knots, 10–15 knots, 15–20 knots, and > 20 knots).

The equations are:

$$\text{Mean traffic}_{Cl(x,y)} = \frac{1}{n} \sum_{k=1}^n \text{Daily traffic}_{Cl(x,y)}$$

where *Cl* is the vessel category considered, (x,y) are the coordinates of the 1 km² grid cell, and *n* is the number of days corresponding to the period (year or month).

$$\text{Traffic percentile}_{T\alpha_{ALL}(x,y)} = \text{Percentile}_{T\alpha_{Cl}}(\text{Daily traffic}_{ALL(x,y)})$$

where α is the considered percentile of the daily traffic distribution for the period T (year, month). These percentiles are computed for all vessel traffic only (Fig. 2).

Overall, a total of 299 maps are presented. A common exponential six-colour palette was used for displaying the traffic density for the whole atlas (Table 4). White corresponds to null traffic. The allocation of traffic density to colours follows a geometric series with a doubling ratio. This allows highlighting the densest traffic areas while keeping the differences in low traffic densities visible.

For each map, the cumulative histogram of the mapped non-null traffic density per 1 km² grid cell is provided in a superimposed bar chart, where each bar corresponds to the traffic density intervals of the map palette (Table 4). The total number of 1 km² grid cells containing non-null traffic is also provided below the palette as well as the sum of the daily traffic. These statistics can be used to compare regional traffic among maps. The total traffic density per 1 km² grid cell for the map period is the product of the mapped daily traffic values per 1 km² grid cell

times the number of days. The total traffic is the sum of the daily traffic times the number of days.

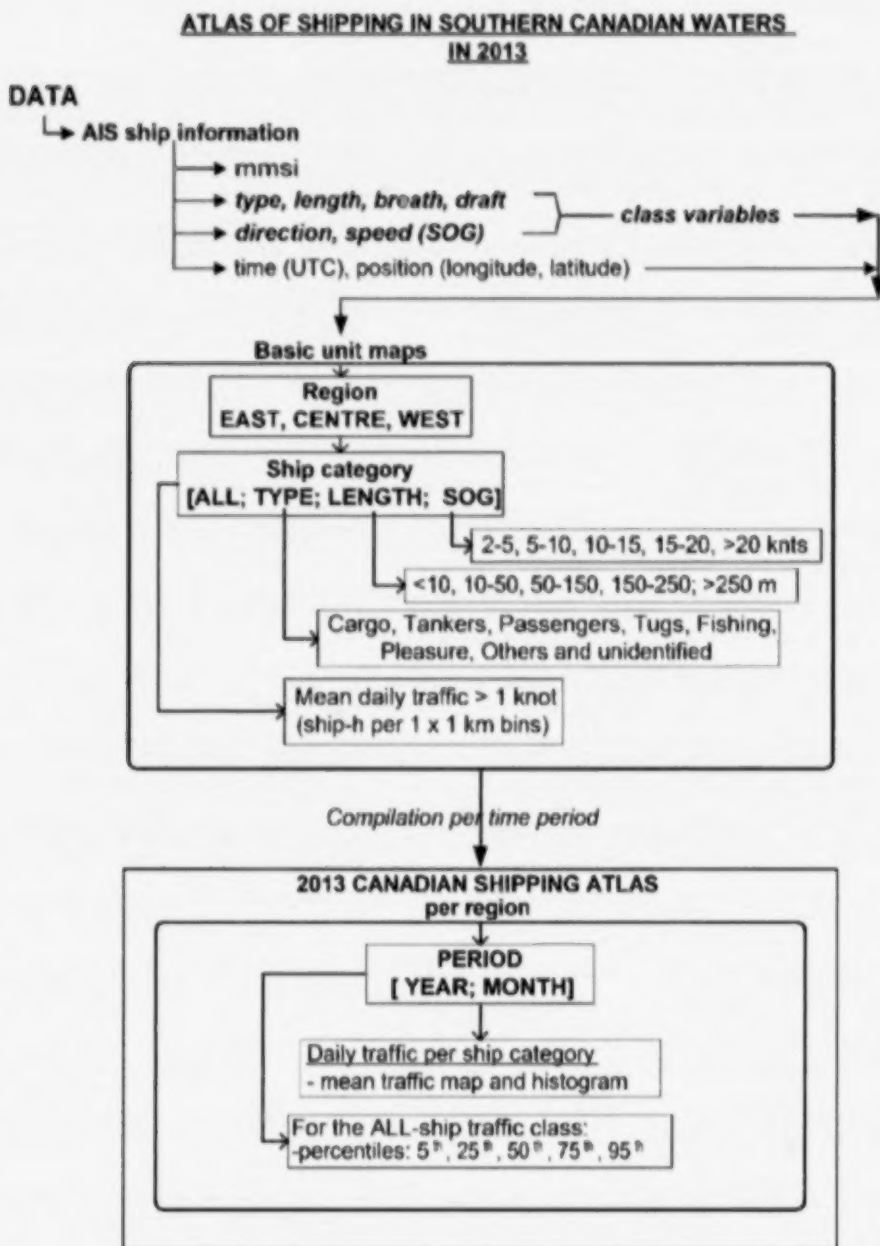

Figure 2. Flow diagram of the AIS data processing for computing the various shipping traffic maps of the atlas.

Table 4. Colour palette used to display the AIS shipping traffic in the atlas maps.

Traffic (ship-h per 1 km² grid cell)	Color	Cumulative histogram traffic density class
No traffic	white	nil
> 0 to 0.0025	dark blue	1
> 0.0025 to 0.005	cyan	2
> 0.005 to 0.01	green	3
> 0.01 to 0.02	yellow	4
> 0.02 to 0.04	orange	5
> 0.04	red	6

3. RESULTS

The atlas maps are arranged by year and by month and are presented in sections 7 and 8 of this report. In each section, the maps of all ship traffic statistics are presented first, then the maps of the mean traffic per ship length and ship SOG categories. How to properly interpret the traffic percentile maps is indicated in the figure legends and the Discussion. These total traffic percentile maps are effective for rapidly locating the high traffic density areas. For example, the 5th or 25th traffic percentile maps reveal areas where the traffic is most intense, having been respectively visited at least 95% or 75% of the days in the considered period. Inversely, the null traffic areas on the 95th traffic percentile map indicate low density areas where there was no traffic at least 95% of the days.

4. DISCUSSION

The maps presented in this report refine the large-scale satellite-based LRIT traffic maps provided by Koropatnick et al. (2012) for a larger area Northwest Atlantic and ranges not usually reachable by RF communication to coastal antenna. The atlas provides high-resolution traffic density maps for a larger shipping traffic fraction than LRIT traffic for Eastern Canadian waters, using a precise traffic-density metric and detailed layers for supporting several marine spatial planning tasks. It offers a reasonable representation of the present traffic throughout the annual cycle for different ship types, length classes and sailing speeds, within at least a 100 km radius of the coastline. However, the user must recognize the limitations of this atlas, especially that only AIS-equipped vessels are considered. Although AIS traffic includes almost all merchant shipping, a fraction of the total traffic is still missing. For instance, although part of the fishing fleet is equipped with AIS, an unknown and spatially variable proportion is not. Despite the large fishing activity in the Gulf of St. Lawrence, little traffic from fishing vessels is reported in AIS data in contrast to Scotian Shelf, where a larger number of vessels appear to use AIS even though they are not required to by law. Given the various contributors to AIS data, knowing the relative contribution of the different ship types appears critical in interpreting total traffic maps.

Another limitation is that the information that was used to separate ships by type and length class is sometimes erroneous or simply lacking, especially for small vessels. Although we invested much time in correcting and completing the received AIS information by consulting ship lists on the Internet, we know that errors are still present and that information is still missing for several ships. AIS identification errors are particularly evident in the < 10 m vessel traffic maps, where we received obviously erroneous data showing small vessels that appeared to sail year-round along regular routes or far offshore². As a consequence, the maps of the ship category "other ships and ships of unidentified type" includes traffic that should have contributed to other maps. Similarly, the traffic maps by ship length may contain ships that are not in the right length class and do not include the proportion of ships with unknown lengths. Therefore the reader must use the atlas for the regional picture it presents on shipping traffic and not put too much emphasis on particular outliers.

The 3 h linear interpolation approach we adopted to correct for the data interruptions successfully filled the ship-track gaps that would otherwise have been numerous. However, this approach sometimes had the unwanted drawback of positioning ships on land when they were changing course to sail around islands or curved coastlines. One way of mitigating this effect is to superimpose the land over the traffic to mask the tracks located on land. This had the unwanted consequence of masking all near-shore grid cells partially covered by land. We therefore chose to leave these false traffic track lines visible, after erasing by hand the most striking ones.

An implicit assumption of the atlas is that the fraction of the total fleet equipped with AIS did not change over the annual cycle. This is likely, but we cannot confirm it is true. It is also possible that the AIS reception antenna network did not entirely and uniformly cover the whole study area and that some traffic was missed in a few locations, continuously or intermittently for some periods. Such reception gaps would, however, mostly occur $> \sim 100$ km offshore. The interpolation approach we used in making the maps has also likely filled most of the embedded reception gaps and bridged time gaps.

For each map, the total sum of the 1 km^2 grid cells where some traffic was encountered is provided. However, it is wrong to interpret this as the area covered by shipping for the considered period, since the physical footprints of ships are much less than 1 km^2 and ship density varies by grid cell. This value is given to assist in comparing the relative importance of given types of traffic throughout the annual atlas. It can be used in combination with the corresponding total daily traffic.

The maps of the daily traffic density percentiles reveal different properties of the total shipping traffic than the maps of the single central statistic (i.e., mean) used elsewhere in the atlas. Their interest for marine spatial planning is to provide, for each 1 km^2 bin, how the daily traffic was distributed at a given location within the month or the whole year. For example, if the traffic was constant throughout the period, all traffic percentiles for this location would have a traffic density equal to the mean because of the uniform probability distribution of the traffic. If

² For example, an *mmsi* number on the < 10 m vessel traffic maps corresponds to the Atlantic Osprey, a ~ 40 m anchor handling-ship regularly transiting between St. John's, Newfoundland, and the Hibernia offshore oil drilling platform.

the traffic was nil half of the days, then the traffic density percentiles $< 50\%$ would have a traffic density of zero. The mean would show some traffic at the location, but the absence of traffic for half of the days would go unnoticed. Likewise, if the traffic was very intense on a few days (of the month or year) and nil the other days, then all traffic percentiles but the highest (e.g., 95%) would have a zero traffic density. This would clearly show the highly sporadic nature of the traffic at this location. On the contrary, when the low traffic density percentiles (e.g., 5% or 25%) are not zero at a given location, this location is likely part of a regularly used sea route. Another interest of the traffic density percentile maps is to provide values of the traffic density associated with sea routes and busy traffic hot spots (e.g., daily traffic density in the 75th or 95th percentiles). When considered over the whole map, the series of traffic density percentiles illustrate how the traffic is spatially distributed over the month or year and its density better than mean traffic density, which blurs the information by averaging over the whole month.

5. ACKNOWLEDGMENTS

This work was supported by Fisheries and Oceans Canada. We are grateful to Michel Desparois and Jean-François Coutu for access to the AIS DFO–Coast Guard data. We thank Cédric Gervaise and Bazile Kinda of the Chair Chorus of Grenoble Institute of Technology for the initial AIS decoding Python code, Jean-Philippe Lapierre for his help in the acquisition and storing of the AIS data stream from the server, and Gilles Fortin for his help with GIS and geographic data. Thanks to Laure Devine for her editorial work and contribution to improve the readability of the report, and to Scott Coffen-Smouth and Gilles H. Tremblay for reviewing the manuscript.
